Sample report: GSE235717_GSM7508429

AstroGenetics: the physics of methylation, read on one sample

Specimen whole blood · platform EPIC

Research use only. Not a diagnostic test. Each reading is printed with its commissioning status: *commissioned* means it passed a test sealed before its data was seen; a reading outside what an instrument was tested on is still shown, and says so. The full technical record (intake, calibration, tare, noise gate, safeguards, integrity, and how to run it yourself) is in the HTML report.

The readings, in plain words

Each gauge runs from 0, the floor (below it a cell can no longer hold its identity), through 1, healthy, to saturation, the most the scale can register. Healthy cells sit in the green band around 1. Moving right means the marks are being lost.

Which cells are in the sample

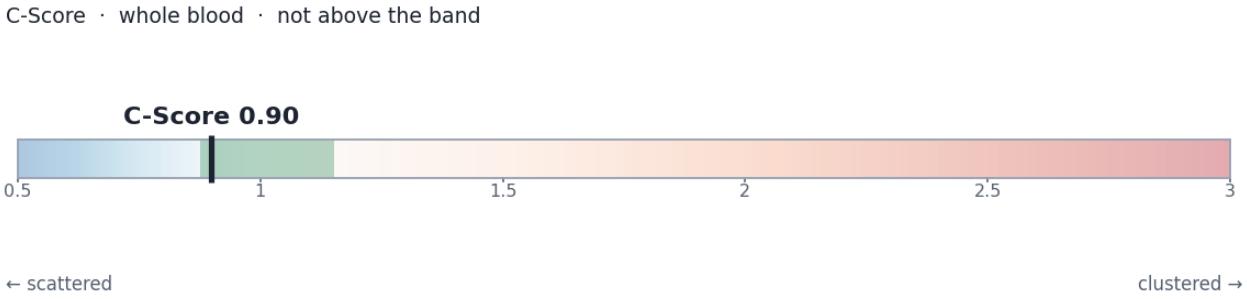

Neutrophils 47 %, CD4 T cells 23 %, CD8 T cells 10 %, NK cells 8 %, read against the 79-cell IAM-Atlas v2.1.

Met-A

How far the neutrophils' tagging level sits from healthy.

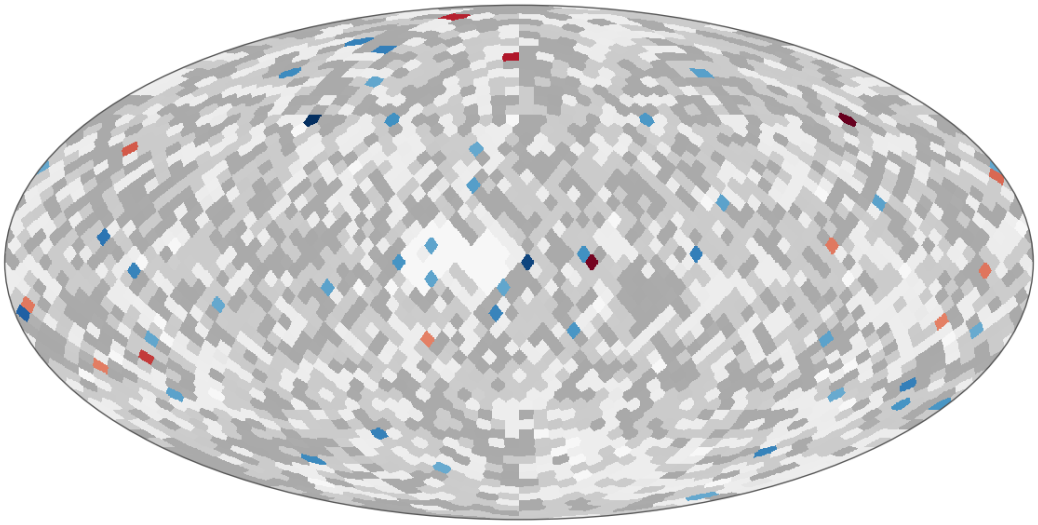

C-Score

Whether the changes are scattered, as in healthy cells, or clustered along the genome.

The sample on the sphere

What changed: this sample laid over healthy neutrophils

matches healthy (grey shade: the healthy cell's tagging)
more disorder than healthy: pattern lost (beyond +2 of its own spread)
more order than healthy (beyond −2)

Met-A 0.979 (tared) C-score 0.90 (tared) · 53 of 3072 pixels changed

Each point is one place in the genome. Grey means the same as a healthy cell. Color means different: a few scattered colored points are ordinary; colored patches mean the changes are bunched together along the genome.
