

Same physics, same ruler as the cell. Isolated spent stars sit above healthy but are capped below breach; only collapse-capable cores reach it.

How astro-genetics reads a star

The star's A_{IAM} (core mass / saturation mass) is shown on the cellular ruler: gravitational saturation $A_{IAM}=1$ maps to the cellular breach at 1.10, because collapse and cellular breach are the same no-return event. An isolated white dwarf such as the Sun is spent (above the healthy reference) yet structurally capped below breach, the same $A_{ceiling}=1/H_{min}$ idea that caps some cell substrates below breach.
